Administrative: Assignment 1

Out tonight, due 4/18 11:59pm

- K-Nearest Neighbor
- Linear classifiers: SVM, Softmax
- Two-layer neural network
- Image features

Administrative: Python + Numpy

CS231n Convolutional Neural Networks for Visual Recognition

Python Numpy Tutorial

This tutorial was contributed by [Justin Johnson](#).

We will use the Python programming language for all assignments in this course. Python is a great general-purpose programming language on its own, but with the help of a few popular libraries (numpy, scipy, matplotlib) it becomes a powerful environment for scientific computing.

We expect that many of you will have some experience with Python and numpy; for the rest of you, this section will serve as a quick crash course both on the Python programming language and on the use of Python for scientific computing.

<http://cs231n.github.io/python-numpy-tutorial/>

Administrative: Google Cloud

Google Cloud Tutorial

For the class project and assignments, we offer an option to use Google Compute Engine for developing and testing your implementations. This tutorial lists the necessary steps of working on the assignments using Google Cloud. For each assignment, we will provide you with an image containing the starter code and all dependencies that you need to complete the assignment. This tutorial goes through how to set up your own Google Compute Engine (GCE)

<http://cs231n.github.io/gce-tutorial/>

Image Classification: A core task in Computer Vision

What the computer sees

An image is just a big grid of numbers between [0, 255]:

e.g. 800 x 600 x 3
(3 channels RGB)

Challenges: Viewpoint variation

```
[1185 112 188 111 184 99 186 99 96 183 112 119 184 97 93 87]

An image classifier

```
def classify_image(image):  
    # Some magic here?  
    return class_label
```

Unlike e.g. sorting a list of numbers,

no obvious way to hard-code the algorithm for
recognizing a cat, or other classes.

Attempts have been made

John Canny, "A Computational Approach to Edge Detection", IEEE TPAMI 1986

Data-Driven Approach

1. Collect a dataset of images and labels
2. Use Machine Learning to train a classifier
3. Evaluate the classifier on new images

Example training set

```
def train(images, labels):  
    # Machine learning!  
    return model
```

```
def predict(model, test_images):  
    # Use model to predict labels  
    return test_labels
```

airplane

automobile

bird

cat

deer

First classifier: Nearest Neighbor

```
def train(images, labels):  
    # Machine learning!  
    return model
```

Memorize all
data and labels

```
def predict(model, test_images):  
    # Use model to predict labels  
    return test_labels
```

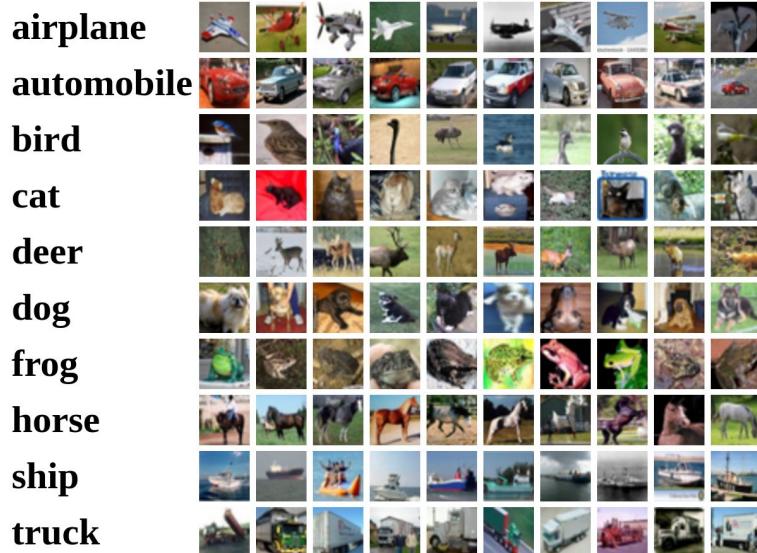

Predict the label
of the most similar
training image

Example Dataset: CIFAR10

10 classes

50,000 training images

10,000 testing images

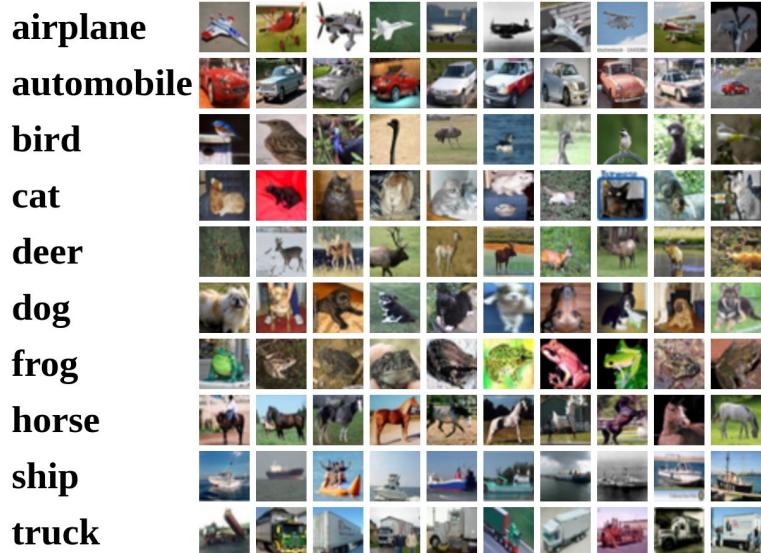

Alex Krizhevsky, "Learning Multiple Layers of Features from Tiny Images", Technical Report, 2009.

Example Dataset: CIFAR10

10 classes

50,000 training images

10,000 testing images

Test images and nearest neighbors

Alex Krizhevsky, "Learning Multiple Layers of Features from Tiny Images", Technical Report, 2009.

Distance Metric to compare images

L1 distance:

$$d_1(I_1, I_2) = \sum_p |I_1^p - I_2^p|$$

        for i in xrange(num_test):
            # find the nearest training image to the i'th test image
            # using the L1 distance (sum of absolute value differences)
            distances = np.sum(np.abs(self.Xtr - X[i,:]), axis = 1)
            min_index = np.argmin(distances) # get the index with smallest distance
            Ypred[i] = self.ytr[min_index] # predict the label of the nearest example

        return Ypred

```

Nearest Neighbor classifier

Q: With N examples, how fast are training and prediction?

A: Train O(1), predict O(N)

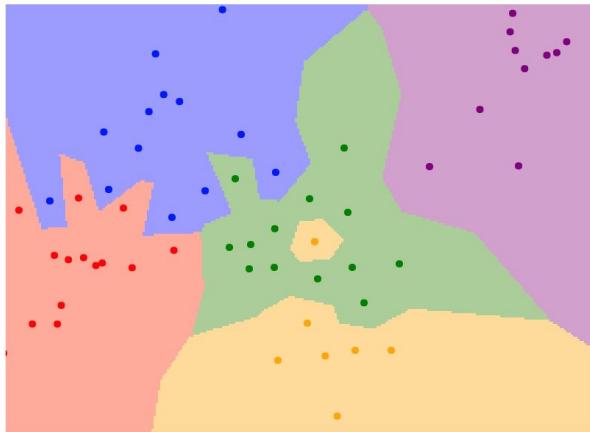

This is bad: we want classifiers that are **fast** at prediction; **slow** for training is ok

What does this look like?

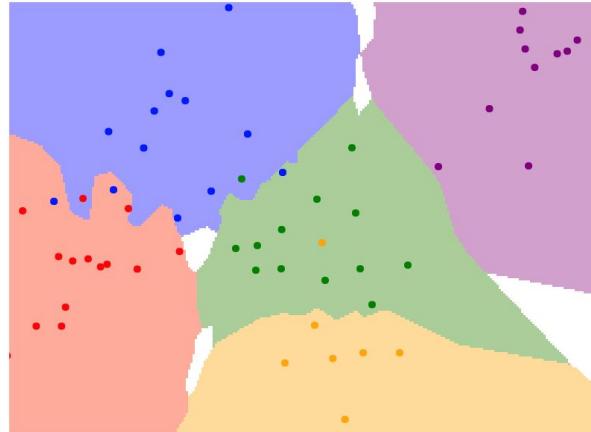

K-Nearest Neighbors

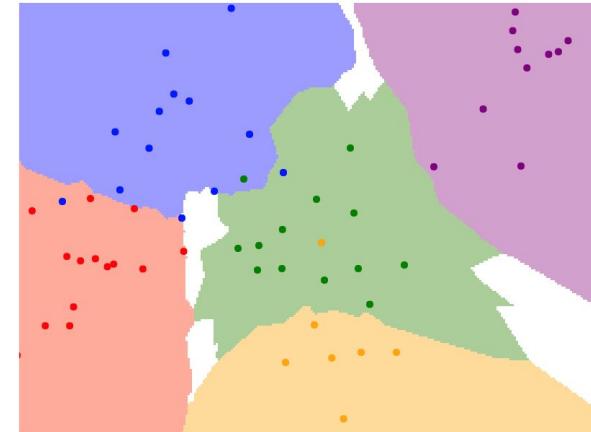

Instead of copying label from nearest neighbor,
take **majority vote** from K closest points

$K = 1$

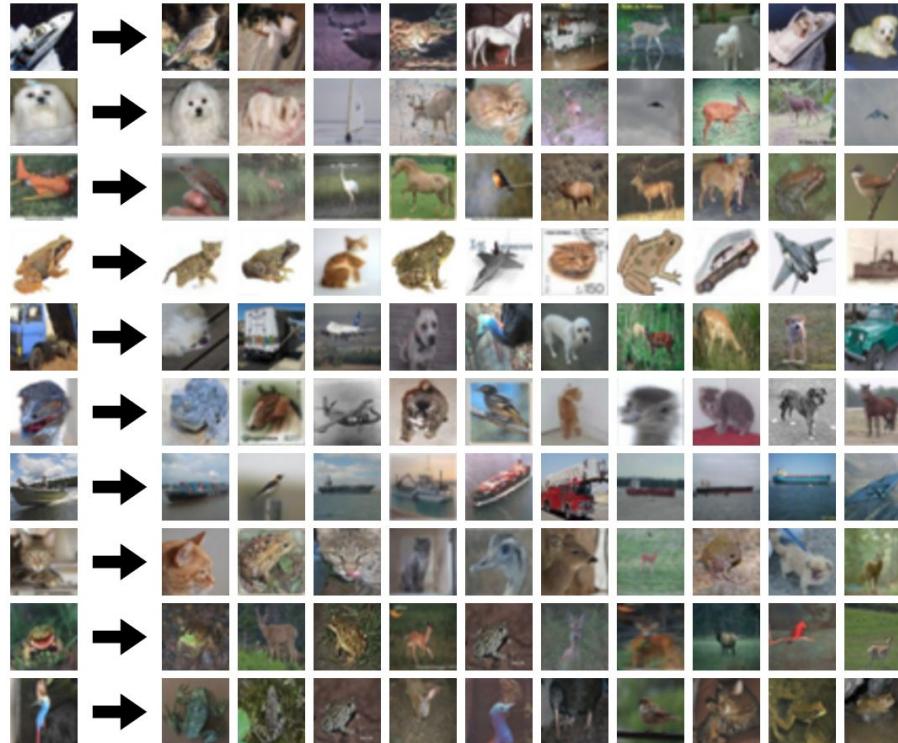

$K = 3$

$K = 5$

What does this look like?

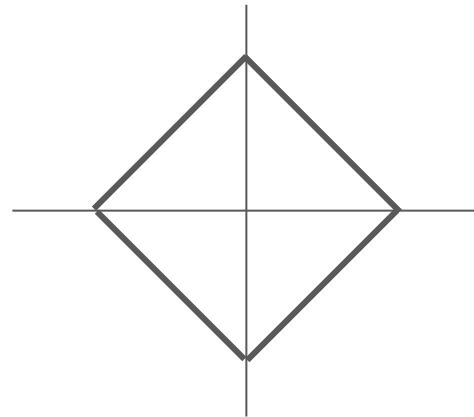

What does this look like?

K-Nearest Neighbors: Distance Metric

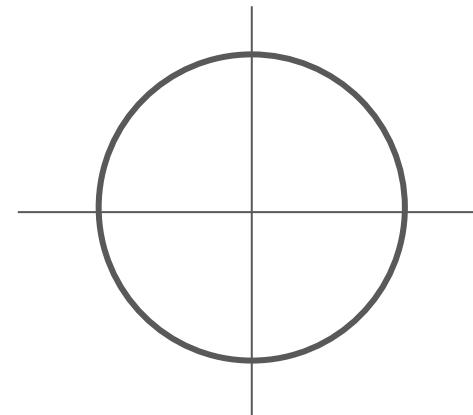

L1 (Manhattan) distance

$$d_1(I_1, I_2) = \sum_p |I_1^p - I_2^p|$$

L2 (Euclidean) distance

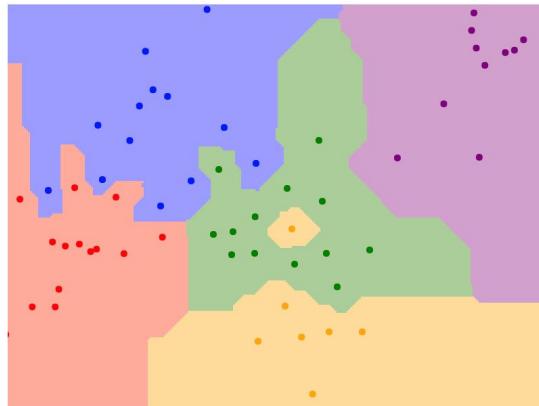

$$d_2(I_1, I_2) = \sqrt{\sum_p (I_1^p - I_2^p)^2}$$

K-Nearest Neighbors: Distance Metric

L1 (Manhattan) distance

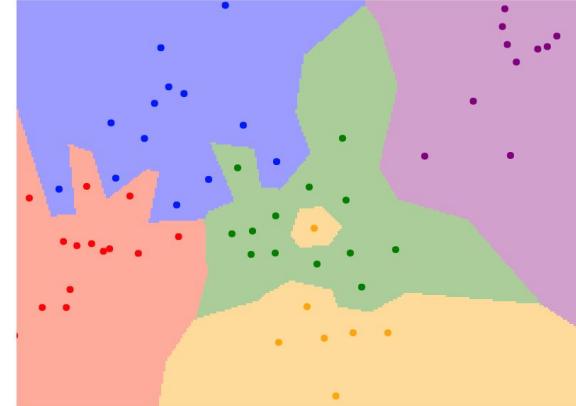

$$d_1(I_1, I_2) = \sum_p |I_1^p - I_2^p|$$

$K = 1$

L2 (Euclidean) distance

$$d_2(I_1, I_2) = \sqrt{\sum_p (I_1^p - I_2^p)^2}$$

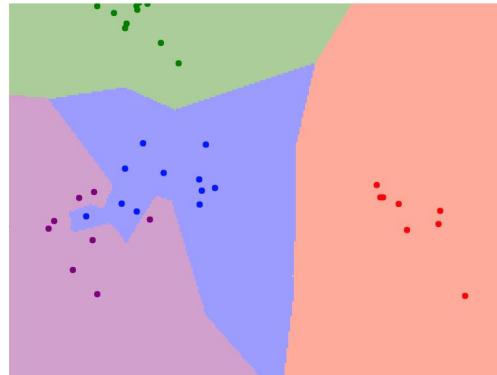

$K = 1$

K-Nearest Neighbors: Demo Time

K-Nearest Neighbors Demo

This interactive demo lets you explore the K-Nearest Neighbors algorithm for classification. Each point in the plane is colored with the class that would be assigned to it using the K-Nearest Neighbors algorithm. Points for which the K-Nearest Neighbor algorithm results in a tie are colored white.

You can move points around by clicking and dragging!

Hyperparameters

What is the best value of k to use?

What is the best **distance** to use?

These are **hyperparameters**: choices about the algorithm that we set rather than learn

Hyperparameters

What is the best value of k to use?

What is the best **distance** to use?

These are **hyperparameters**: choices about the algorithm that we set rather than learn

Very problem-dependent.

Must try them all out and see what works best.

Setting Hyperparameters

Idea #1: Choose hyperparameters
that work best on the data

Your Dataset

Setting Hyperparameters

Idea #1: Choose hyperparameters
that work best on the data

BAD: $K = 1$ always works
perfectly on training data

Your Dataset

Setting Hyperparameters

Idea #1: Choose hyperparameters that work best on the data

BAD: $K = 1$ always works perfectly on training data

Your Dataset

Idea #2: Split data into **train** and **test**, choose hyperparameters that work best on test data

train

test

Your Dataset

Idea #2: Split data into **train** and **test**, choose hyperparameters that work best on test data

BAD: No idea how algorithm will perform on new data

train

test

Idea #3: Split data into **train**, **val**, and **test**; choose hyperparameters on val and evaluate on test

Better!

train

validation

test

Setting Hyperparameters

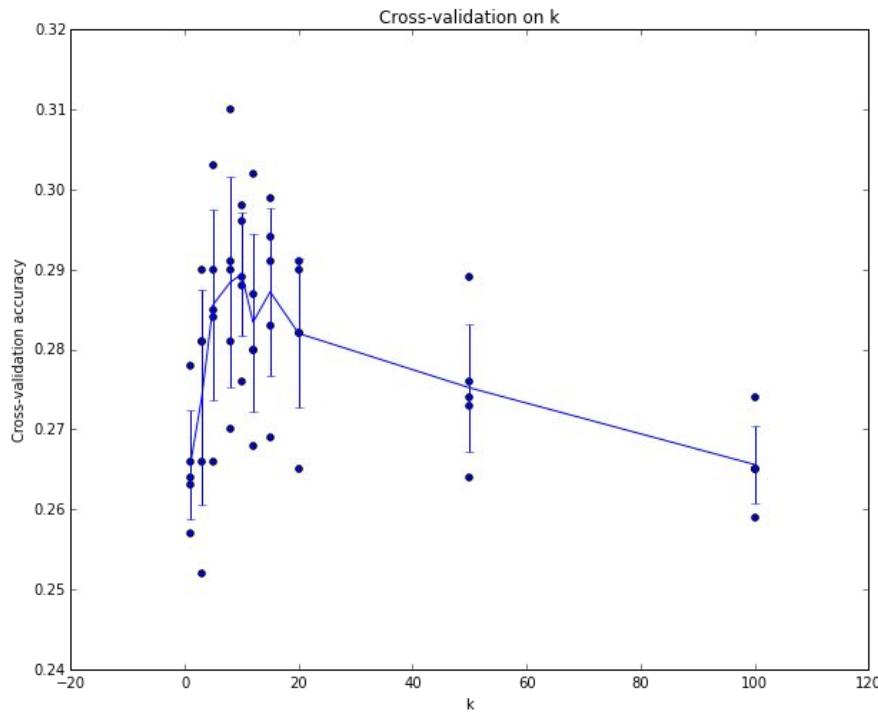

Your Dataset

Idea #4: Cross-Validation: Split data into **folds**,
try each fold as validation and average the results

fold 1	fold 2	fold 3	fold 4	fold 5	test
fold 1	fold 2	fold 3	fold 4	fold 5	test
fold 1	fold 2	fold 3	fold 4	fold 5	test

Useful for small datasets, but not used too frequently in deep learning

Setting Hyperparameters

Example of
5-fold cross-validation
for the value of **k**.

Each point: single
outcome.

The line goes
through the mean, bars
indicated standard
deviation

(Seems that $k \approx 7$ works best
for this data)

k-Nearest Neighbor on images **never used**.

- Very slow at test time
- Distance metrics on pixels are not informative

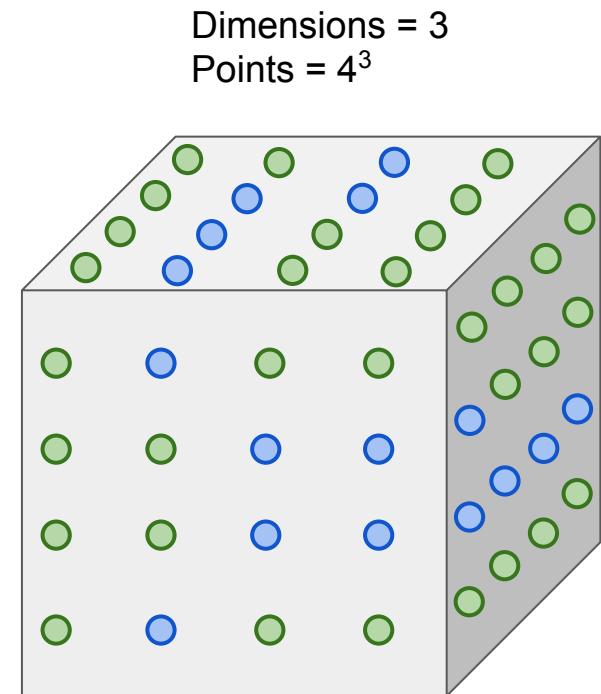

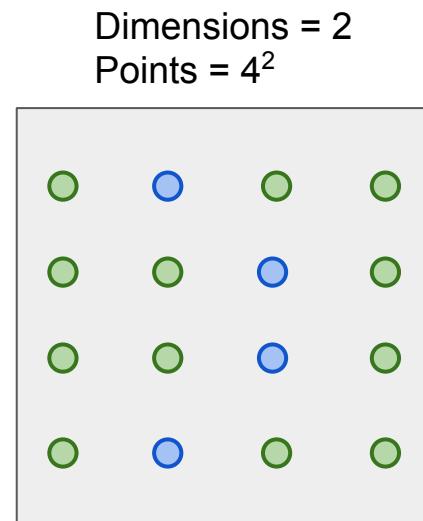

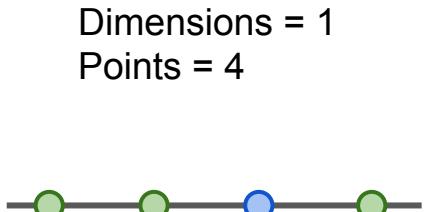

(all 3 images have same L2 distance to the one on the left)

Original image is
CC0 public domain

k-Nearest Neighbor on images **never** used.

- Curse of dimensionality

K-Nearest Neighbors: Summary

In **Image classification** we start with a **training set** of images and labels, and must predict labels on the **test set**

The **K-Nearest Neighbors** classifier predicts labels based on nearest training examples

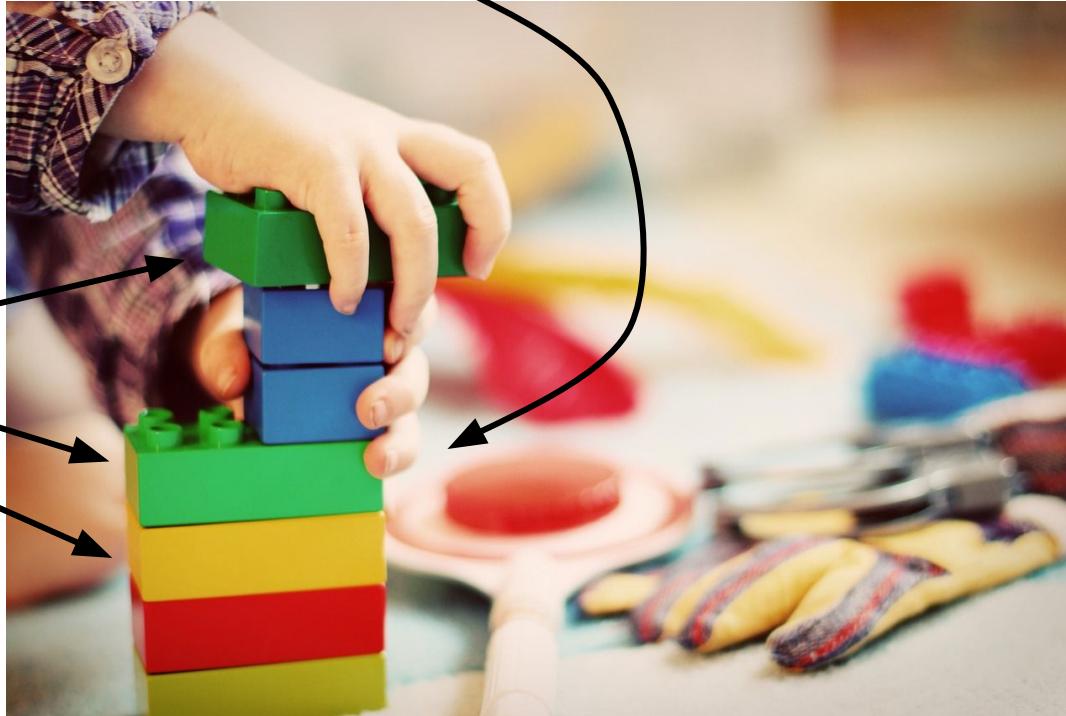

Distance metric and K are **hyperparameters**

Choose hyperparameters using the **validation set**; only run on the test set once at the very end!

Linear Classification

Neural Network

Linear
classifiers

Recall CIFAR10

airplane

automobile

bird

cat

deer

dog

frog

horse

ship

truck

50,000 training images
each image is **32x32x3**

10,000 test images.

Parametric Approach

Image

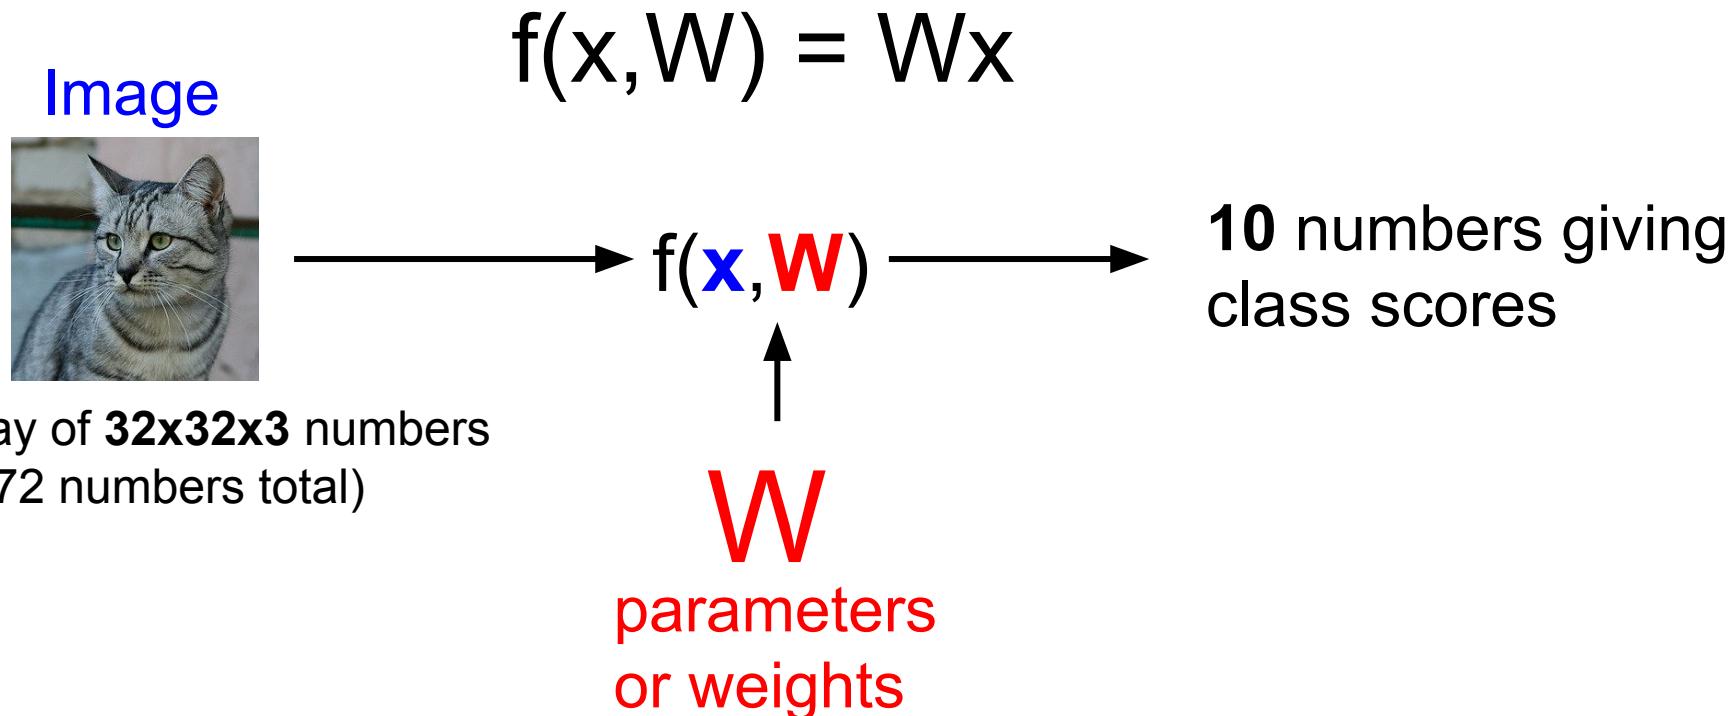

Array of **32x32x3** numbers
(3072 numbers total)

$$\xrightarrow{f(x, W)}$$

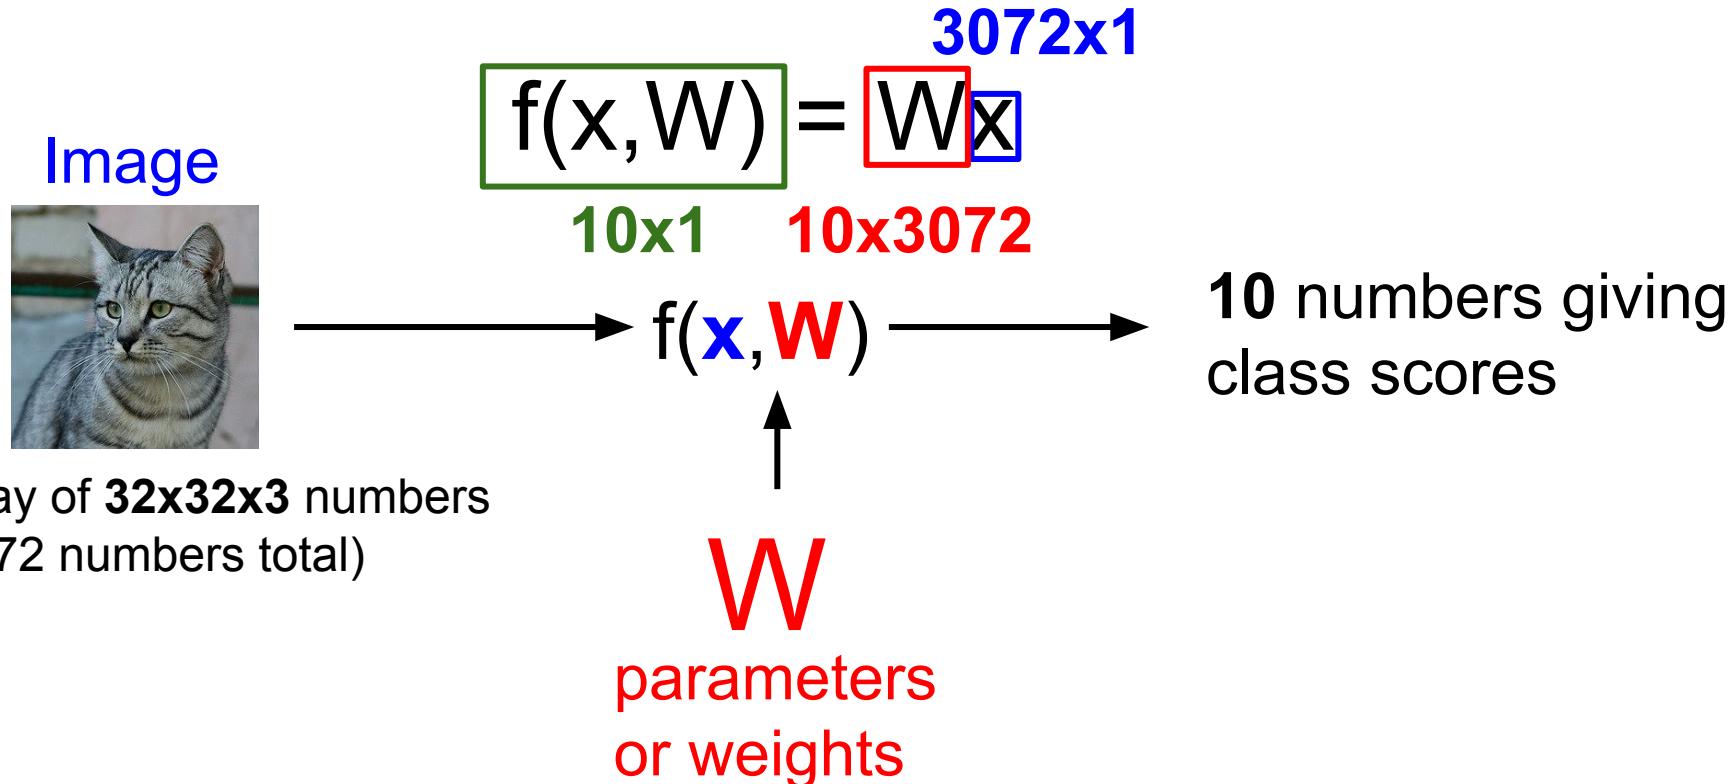

W
parameters
or weights

10 numbers giving
class scores

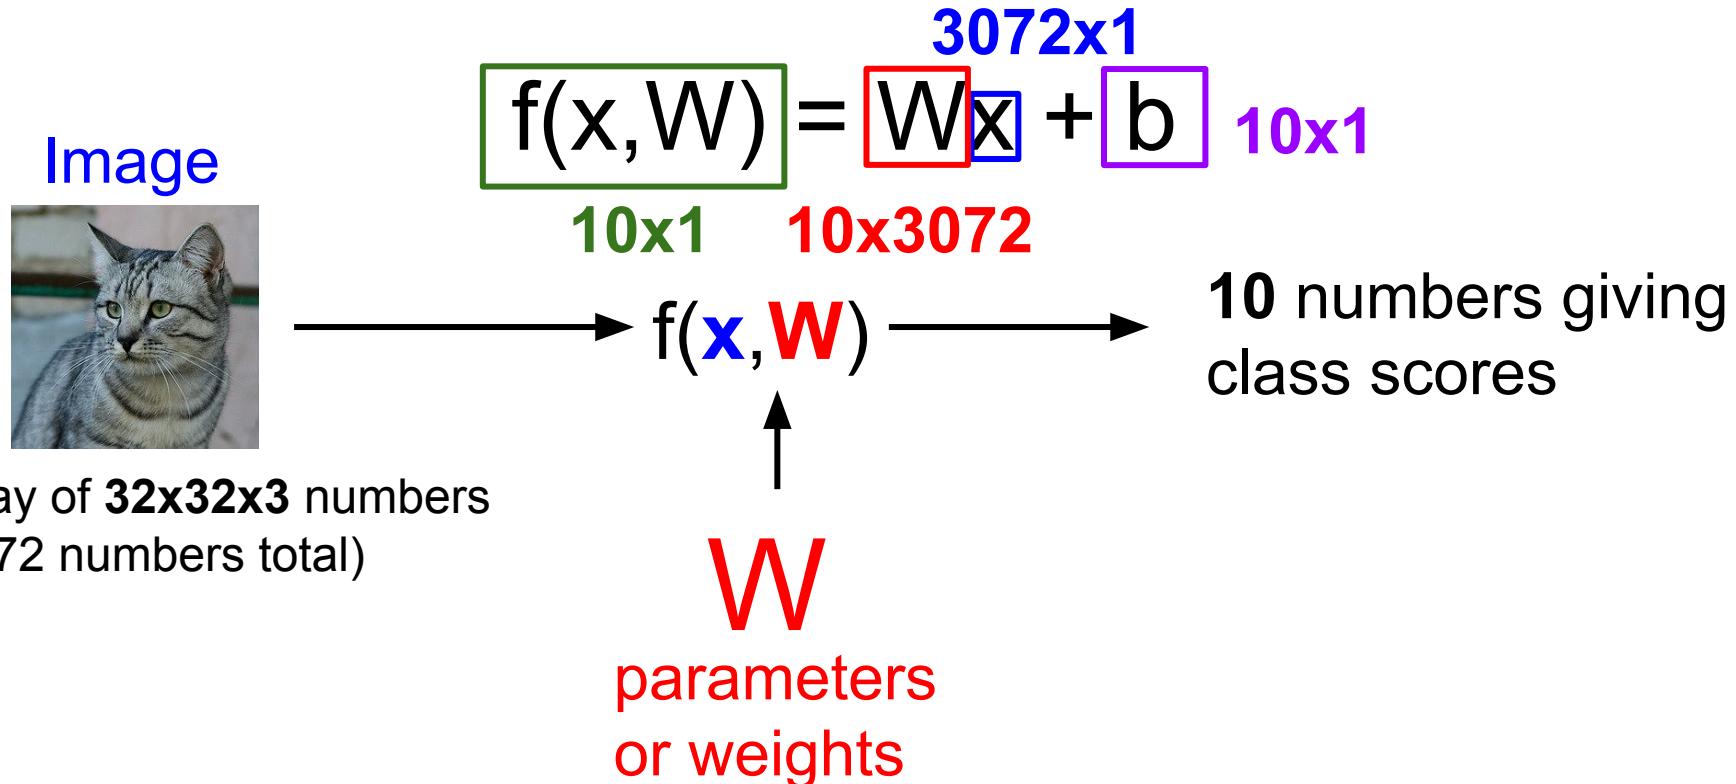

Parametric Approach: Linear Classifier

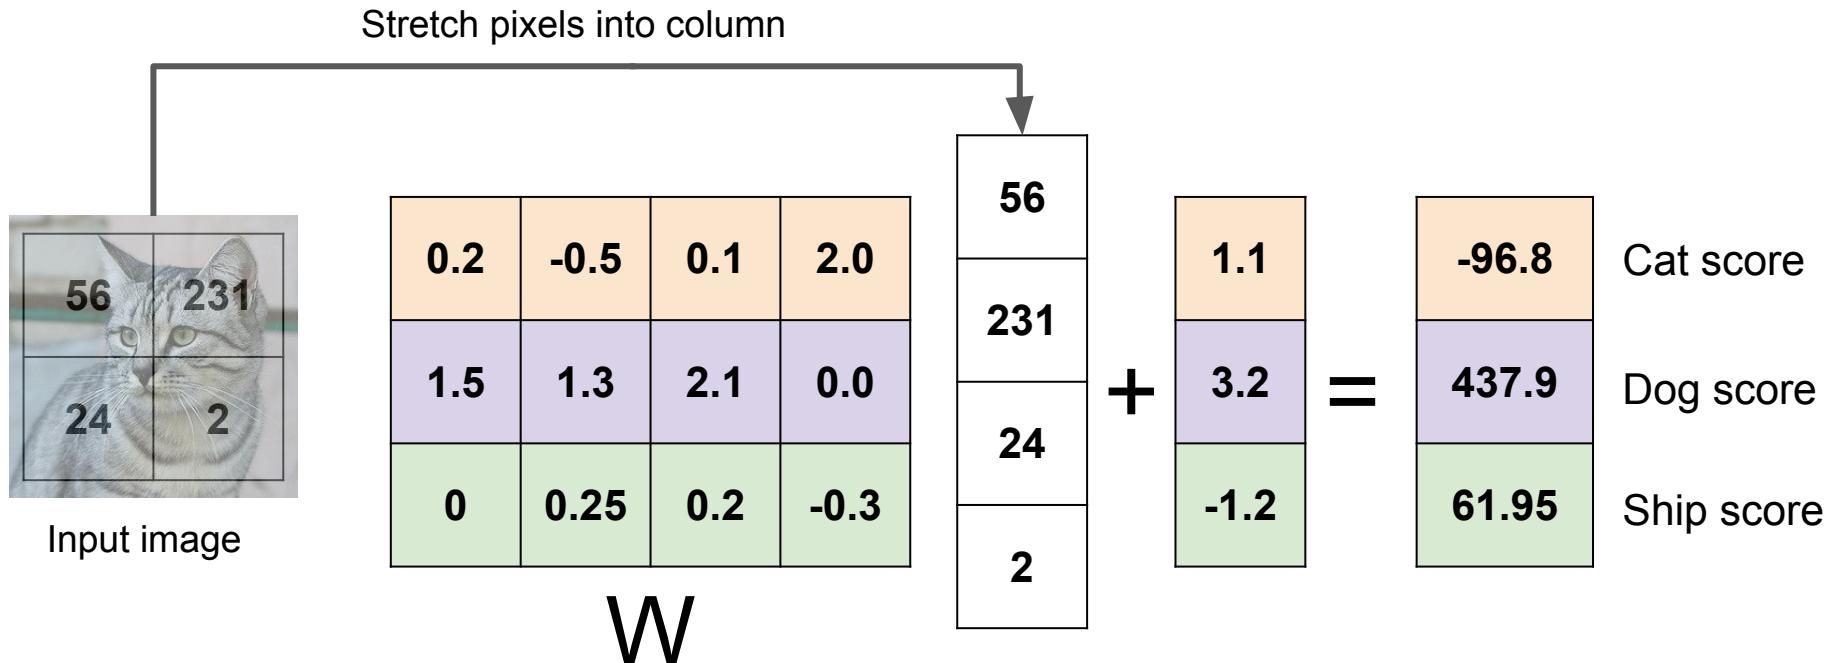

Parametric Approach: Linear Classifier

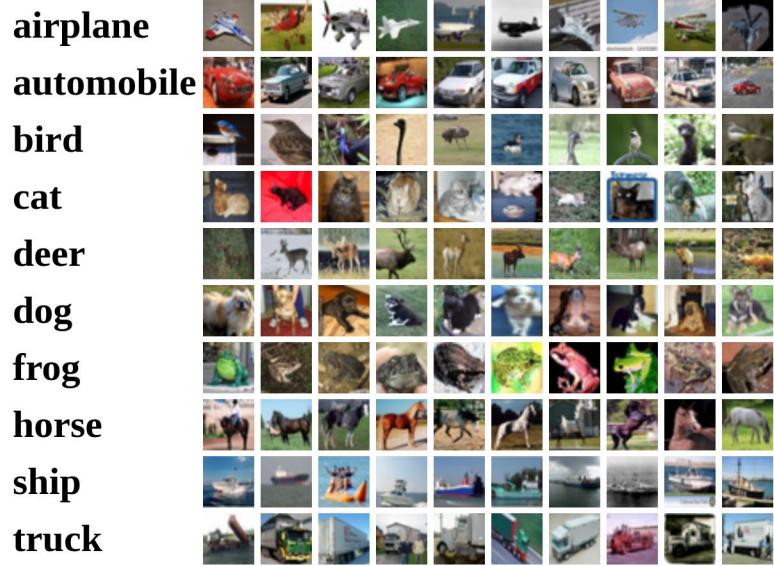

Parametric Approach: Linear Classifier

Example with an image with 4 pixels, and 3 classes (cat/dog/ship)

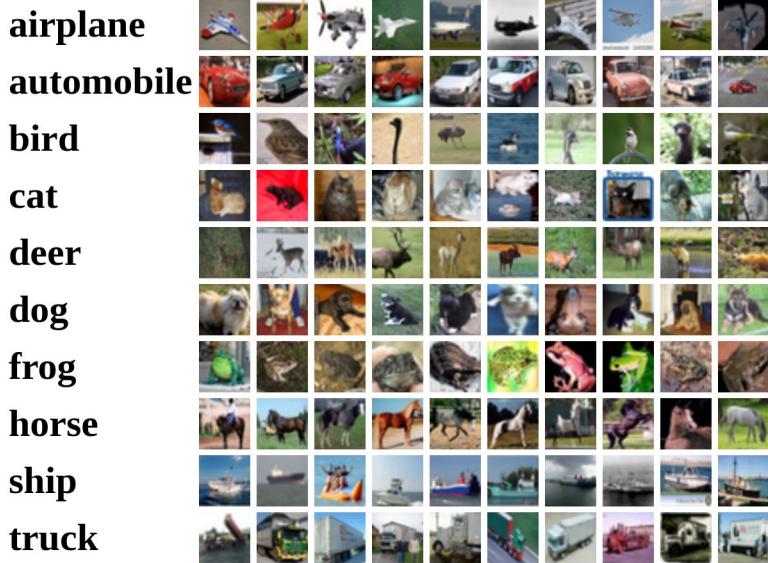

Interpreting a Linear Classifier

$$f(x, W) = Wx + b$$

What is this thing doing?

Interpreting a Linear Classifier

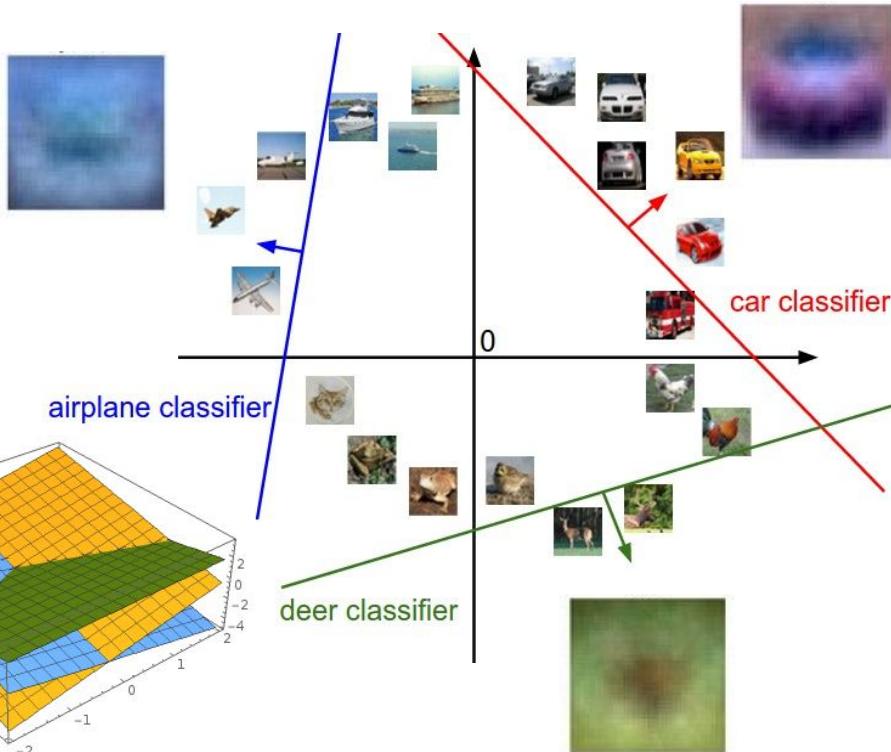

$$f(x, W) = Wx + b$$

Example trained weights
of a linear classifier
trained on CIFAR-10:

Interpreting a Linear Classifier

$$f(x, W) = Wx + b$$

Array of **32x32x3** numbers
(3072 numbers total)

Plot created using [Wolfram Cloud](#)

Hard cases for a linear classifier

Class 1:

number of pixels > 0 odd

Class 2:

number of pixels > 0 even

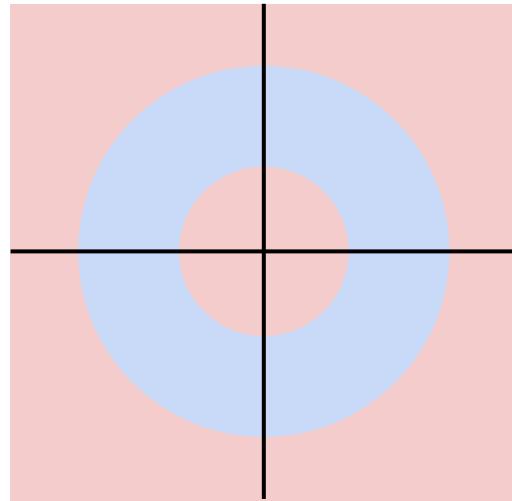

Class 1:

$1 \leq L_2 \text{ norm} \leq 2$

Class 2:

Everything else

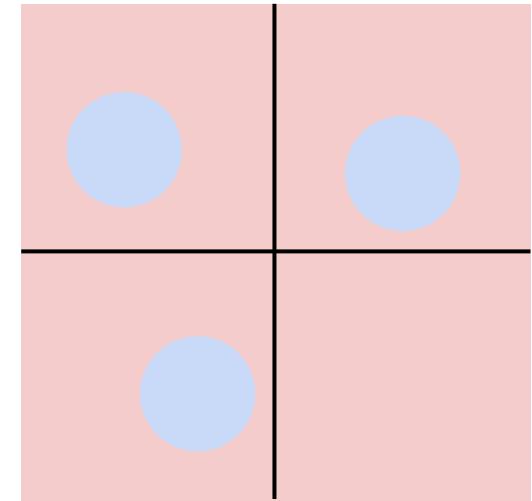

Class 1:

Three modes

Class 2:

Everything else

So far: Defined a (linear) score function $f(x, W) = Wx + b$

Example class scores for 3 images for some W :

How can we tell whether this W is good or bad?

airplane	-3.45	-0.51	3.42
automobile	-8.87	6.04	4.64
bird	0.09	5.31	2.65
cat	2.9	-4.22	5.1
deer	4.48	-4.19	2.64
dog	8.02	3.58	5.55
frog	3.78	4.49	-4.34
horse	1.06	-4.37	-1.5
ship	-0.36	-2.09	-4.79
truck	-0.72	-2.93	6.14

[Cat image](#) by [Nikita](#) is licensed under [CC-BY 2.0](#)

[Car image](#) is [CC0 1.0](#) public domain

[Frog image](#) is in the public domain

$$f(x, W) = Wx + b$$

Coming up:

- Loss function
- Optimization
- ConvNets!

(quantifying what it means to have a “good” W)

(start with random W and find a W that minimizes the loss)

(tweak the functional form of f)
